## Abstract

*Ophiorrhiza reflexa*, a new species from Guangxi, China, is described and illustrated in this study. It is morphologically similar to *O. alatiflora* due to the branched inflorescence, distylous flowers and the tubular-funnelform corolla with five longitudinal wings. The new species can be distinguished from *O. alatiflora* by its erect inflorescence, its smaller and equal-sized calyx lobes 0.5–0.7 mm long, its corolla tubes winged to the middle and the wings straight and its strongly reflexed corolla lobes at anthesis. *Ophiorrhiza reflexa* is assessed as least concern (LC) according to IUCN Categories and Criteria.

**Key words:** China, new taxon, *Ophiorrhiza*, Rubiaceae, taxonomy

## Introduction

*Ophiorrhiza* Linnaeus (1753) is a notably species-rich and taxonomically complicated genus in the family Rubiaceae, comprising about 200–300 species (Deb and Mondal 1997; Chen and Taylor 2011; Li 2020) and mainly distributed in tropical and subtropical Asia (Darwin 1976; Lo 1990; Deb and Mondal 1997; Chen and Taylor 2011; Deng and Huang 2012; Hareesh et al. 2015; Wong 2019; Hu et al. 2021; Schanzer and Nabatov 2022; Liu et al. 2023). Species of the genus are annual or perennial herbs and rarely sub-shrubs that can be easily recognised by their obcordate and compressed fruits, which are dehiscent with two valves along a transverse slit at the top (Darwin 1976; Lo 1990; Chen and Taylor 2011; Wu et al. 2019). Though the genus is well-defined by this distinctive fruit shape, demarcation of species within the genus is sometimes very difficult due to the high morphological variation (Nakamura et al. 2006, 2007; Duan and Lin 2007, 2009; Wu et al. 2017c) and insufficient knowledge of flowers in most species (Hooker 1880; Schanzer 2004; Wu et al. 2017a, b).

China is one of the diversification centres of *Ophiorrhiza*. Approximately 72 species (with 50 endemics) of the genus have been recorded in this country and they are mainly distributed in southern and south-western China, especially in Guangxi Province and Yunnan Province (Chen and Taylor 2011; Huang et al. 2017; Wu et al. 2017a, b, c, 2018; Tu et al. 2018; Duan et al. 2019; Wen et al. 2019; Hu et al. 2021; Liu et al. 2023).

During our field survey in Napo County, western Guangxi, in 2013, we collected a peculiar population of plants in full blossom. The individuals were first identified as *Ophiorrhiza alatiflora* H.S.Lo as they shared similar habitats and morphological characters, such as branched inflorescences, distylous flowers with tubular-funnelform corollas and a corolla with five longitudinal wings. After revisiting the area including the type locality of *O. alatiflora* and further examining the specimens, however, these individuals from Napo County can be distinguished from *O. alatiflora* mainly by their inflorescences which are erect from their earliest developmental stages (vs. drooping when young, then erect), their smaller calyx lobes (0.5–0.7 vs. 0.9–1.8(–2.5) mm long) which are equal in size (vs. usually unequal), the nature of the longitudinal wings on the corolla tube (wings extending from top to middle and straight vs. wings extending along entire length and obviously undulate) and the strongly reflexed corolla lobes (vs. spreading) at anthesis. Therefore, the specimens are assumed to represent an undescribed new taxon, which is here described.

## Material and methods

Most materials are deposited at the Herbarium of Forest Plants in Central South University of Forestry and Technology (**CSFI**). Herbarium acronyms follow Thiers (2023). Morphological observations of the new species were derived from field observations, as well as a study of dry specimens. The morphological terms employed here follow Chen and Taylor (2011). The conservation status of this new species is evaluated, based on field observations in accordance with IUCN Red List guidelines (IUCN 2023).

## Taxonomic treatment

***Ophiorrhiza reflexa* L.Wu & Q.R.Liu, sp nov.**

[urn:lsid:ipni.org:names:77336995-1](https://nomenclature.ipni.org/names/77336995-1)

Figs 1, 2

**Diagnosis.** The new species is most similar to *O. alatiflora*, but can be distinguished from the latter by the inflorescences which are erect from the earliest developmental stages (vs. drooping when young, then erect), the small and equally-sized calyx lobes 0.5–0.7 mm long (vs. 0.9–1.8, sometimes to 2.5 mm long and usually unequal), the longitudinal wings on the corolla tube which run to the middle of the tube and are straight (vs. wings running along entire length and obviously undulate) and the strongly reflexed corolla lobes (vs. spreading) at anthesis.

**Type.** CHINA. Guangxi Zhuang Autonomous Region: Napo County, Pingmeng Town, Guijiao Village, growing in limestone areas, under evergreen broad-leaved forests, rare, 23°0'30"N, 105°51'53"E, 1080 m alt., 25 Oct 2013 (fl.), L. Wu, C. Du & S.S. Mo 4031 (holotype: CSFI 080032!; isotypes: BNU! CSFI! IBK!).

**Description.** Perennial herbs or subshrubs, suberect, up to 100 cm tall. Stems terete to slightly compressed, glabrous. Leaves in subequal pairs; petiole 4–6 cm long, smooth; blade thickly papery, adaxially green, abaxially pale green, broadly ovate to elliptic-ovate, 11–17 × 5–8 cm, glabrous on both surfaces, base broadly cuneate to obtuse, apex acuminate or subacute, margin entire; lat-

**Figure 1.** *Ophiorrhiza revoluta* **A** flowering branch **B** stipule **C** part of inflorescence **D** longitudinally dissected short-styled flower **E** longitudinally dissected long-styled flower **F** capsules. Drawn from the holotype by X.Y. Zeng.

eral veins 9–11 on each side of the mid-rib; stipules caducous, triangular ovate, ca. 1.5 mm long, apex obtuse. Cymes terminal, erect from youngest developmental stages, many-flowered; peduncle stout, 3–6 cm long, puberulent; bracts

linear-lanceolate, 8–19 × 1–3 mm, glabrous on both surfaces, apex acute; pedicels 1–3 mm long, puberulent. Flowers heterostylous. Calyx densely pilosulous to puberulent; hypanthium turbinate, 5-ribbed; lobes 5, equal, 0.5–0.7 mm long, triangular, subglabrous abaxially, with a gland in each sinus. Corolla white or sometimes slightly pink at apex, tubular-funnelform, outside glabrous; tube 1.3–1.5 cm long, outside longitudinally winged from apex to middle, wings straight, ca. 0.8 mm wide; lobes 5, ovate-triangular, ca. 4 × 3 mm, reflexed, inside densely pubescent, apex acute. Stamens 5; anthers linear, 2.5–3 mm long. Stigma bilobed; ovary 2-celled. Long-styled flowers: inside with a ring of white hairs at the middle of the corolla tube and puberulent from the middle up to the throat; stamens included, positioned near the middle of the corolla tube; style densely pubescent; stigma positioned near corolla throat, lobes ovate-elliptic, ca. 1.4 mm long. Short-styled flowers: sparsely pubescent at the middle of the corolla tube; stamens reaching slightly beyond corolla throat, not exerted; style included near the middle of the corolla tube, glabrous; stigma lobes lanceolate-elliptic, 2–3 mm long. Capsules rhomboid, ca. 4 × 9 mm, glabrous.

**Phenology.** Flowering from October to January; fruiting from March to June.

**Distribution and habitat.** *Ophiorrhiza reflexa* grows in moist places under evergreen broad-leaved forests in the limestone region of Napo County, Guangxi, China (Fig. 4).

**Preliminary conservation status.** Three populations of *Ophiorrhiza reflexa* with more than 1000 individuals at each site have been found during our field investigations. The three sites all belong to Laohutiao Provincial Nature Reserve, which is well-protected and not under threat (Tang et al. 2013). All individuals are distributed in an area of ca. 50 km<sup>2</sup> (10 × 5 km) and have remained roughly stable for the past 10 years. According to currently available data, *O. reflexa* is preliminarily assessed as Least Concern (LC) according to IUCN Categories and Criteria (IUCN 2023).

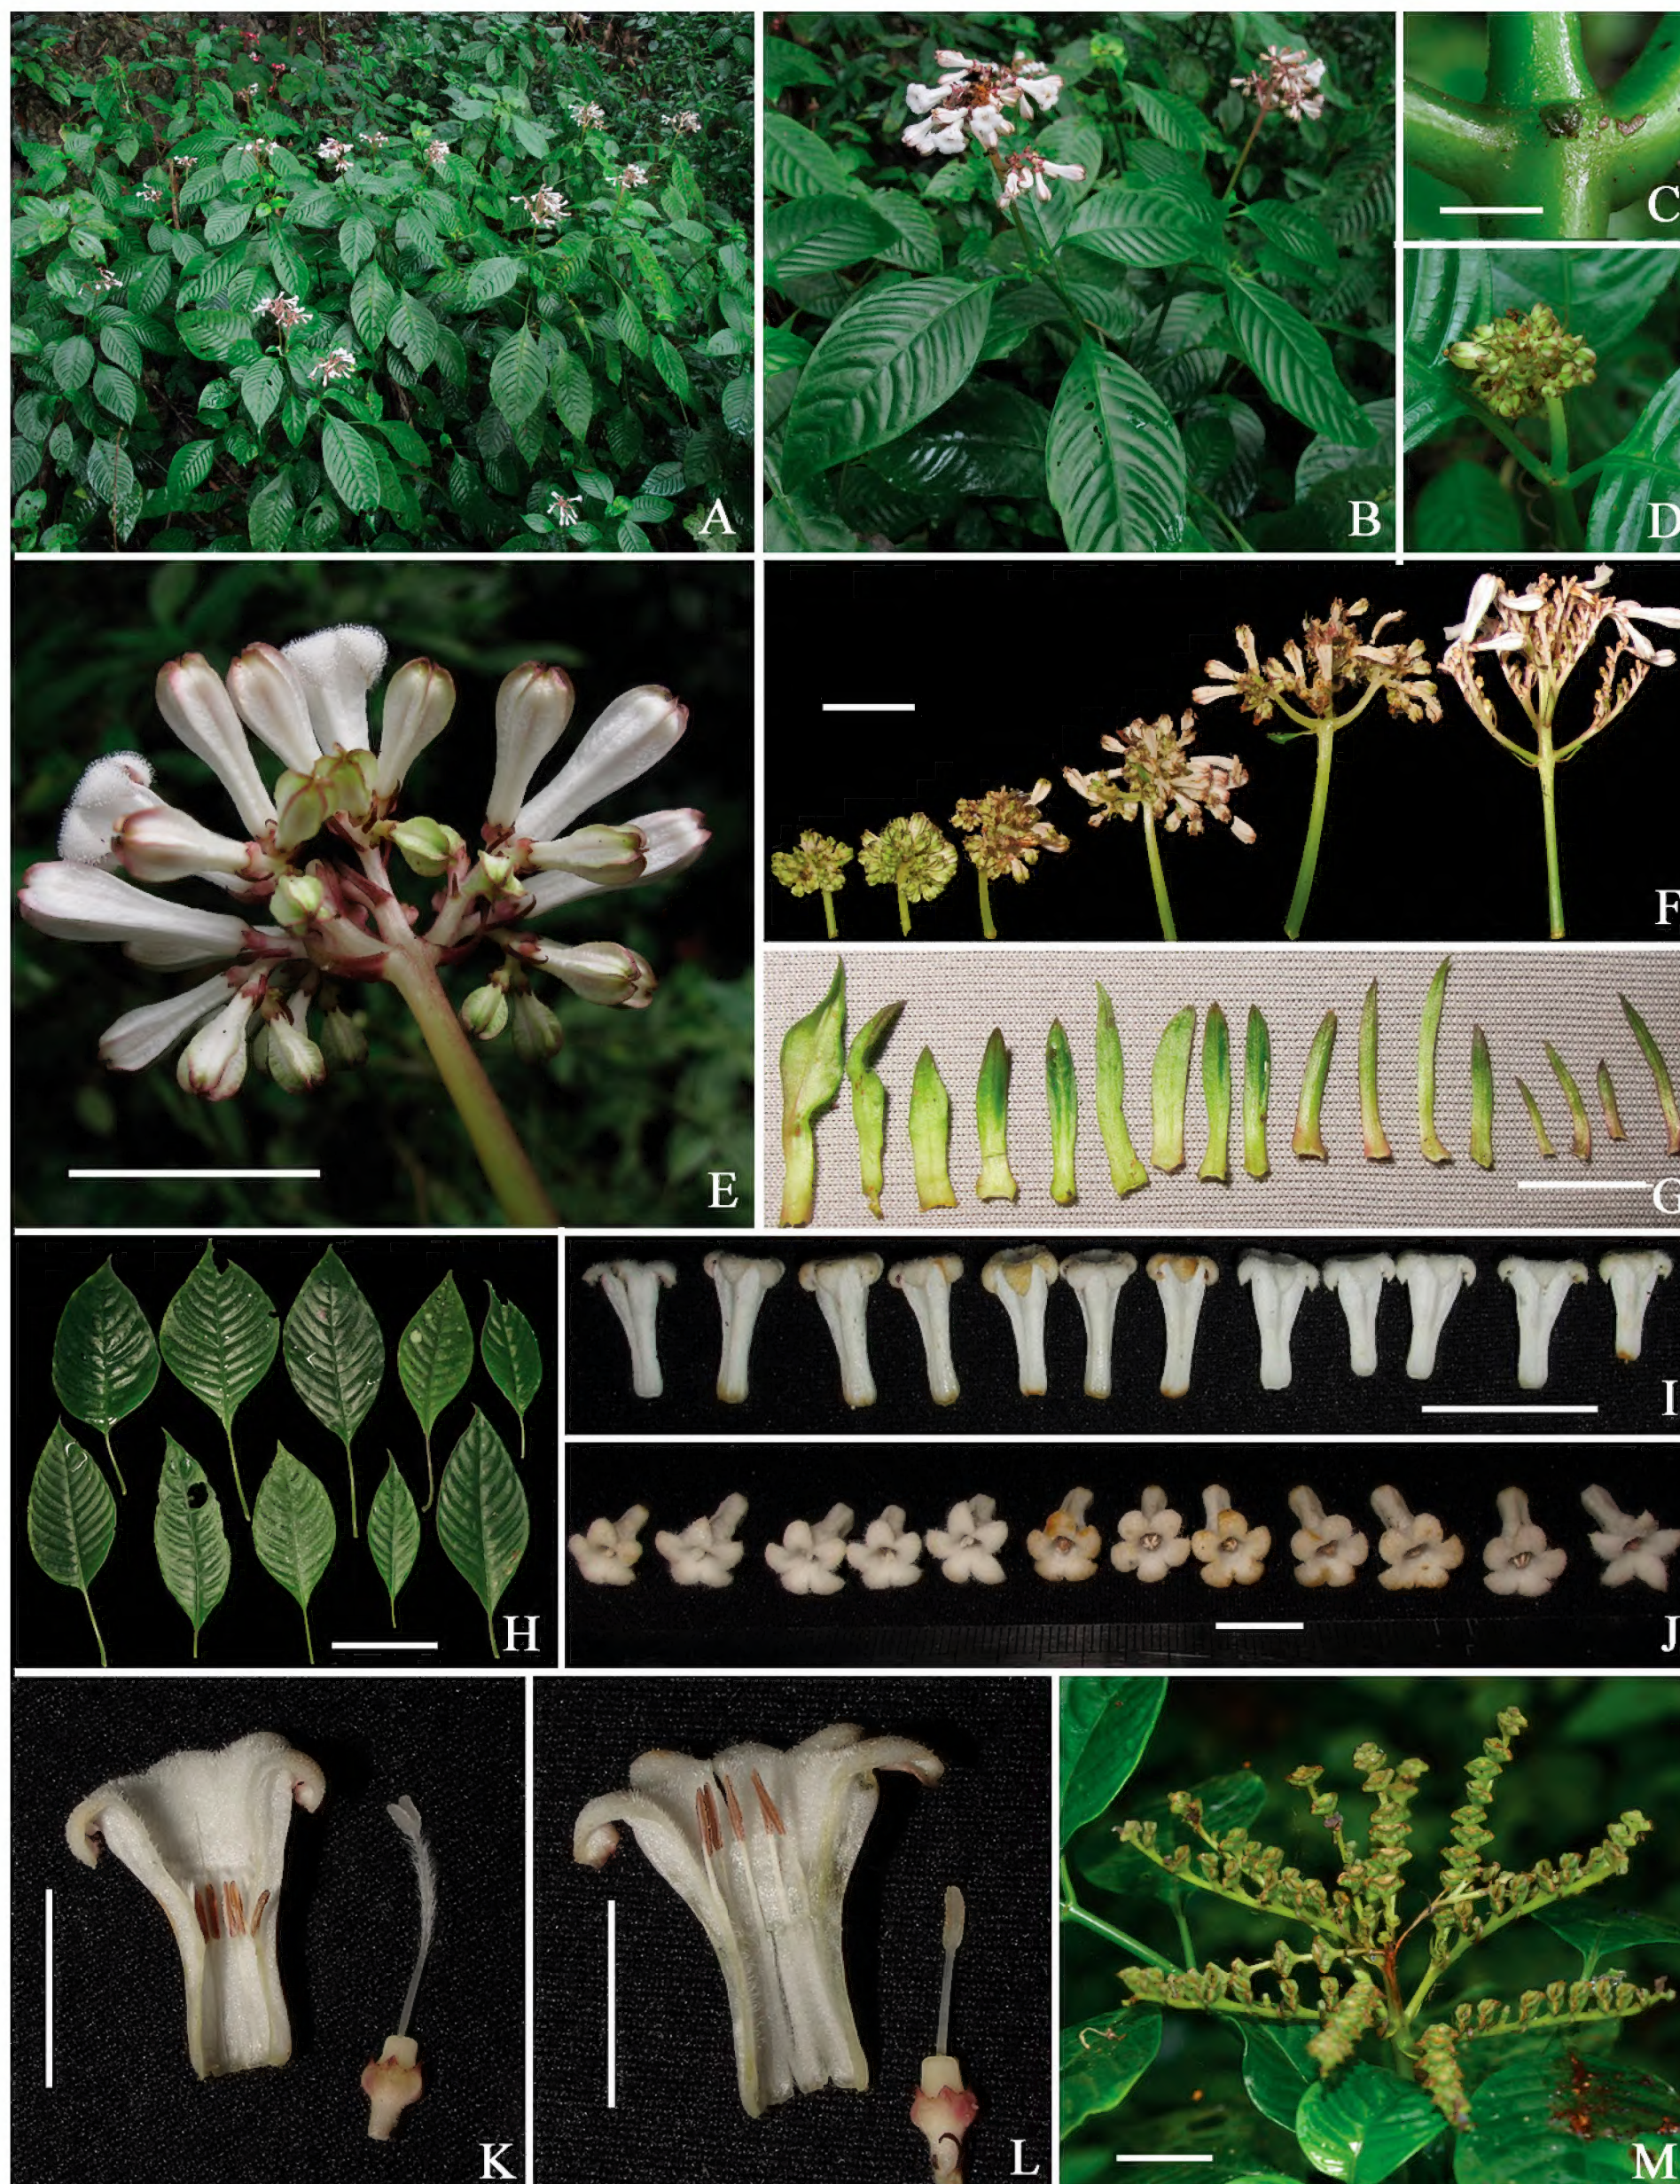

**Additional specimens examined (paratypes).** CHINA. Guangxi Zhuang Autonomous Region: Napo County, Baisheng Town, Nongming Village, 1200 m alt., 14 May 2013 (fr.), L. Wu 3706 (BNU! CSFI!); same locality as holotype, 25 Oct 2013 (fl.), L. Wu, C. Du, S.S. Mo 4033 (BNU! CSFI! IBK!); Napo County, Pingmeng Town, Guigan Village, under evergreen broad-leaved forests, 1100 m alt., 7 Jan 2014 (fl.), L. Wu 4173 (BNU! CSFI!); ibid., 10 May 2017 (fr.), L. Wu & Z.J. Wen 5891 (CSFI!).

**Etymology.** The species epithet refers to the reflexed corolla lobes. The Chinese name is given as ‘fan-ban-she-gen-cao (反瓣蛇根草)’.

**Notes.** *Ophiorrhiza* is a taxonomically difficult genus despite its easy distinction at genus level by the unique fruits. Misidentification or synonymy have become a major problem (Schanzer 2004; Wu et al. 2017c). As mentioned above, the reason is mainly the high morphological variation and insufficient knowledge of important characters, especially flowers (e.g. *Ophiorrhiza nigricans* H.S.Lo was synonymised as *O. japonica* Blume by Duan and Lin (2007); *O. pseudonapoensis* L.Wu & Q.R.Liu has been misidentified as *O. napoensis* H.S. Lo until Liu et al. (2023)).

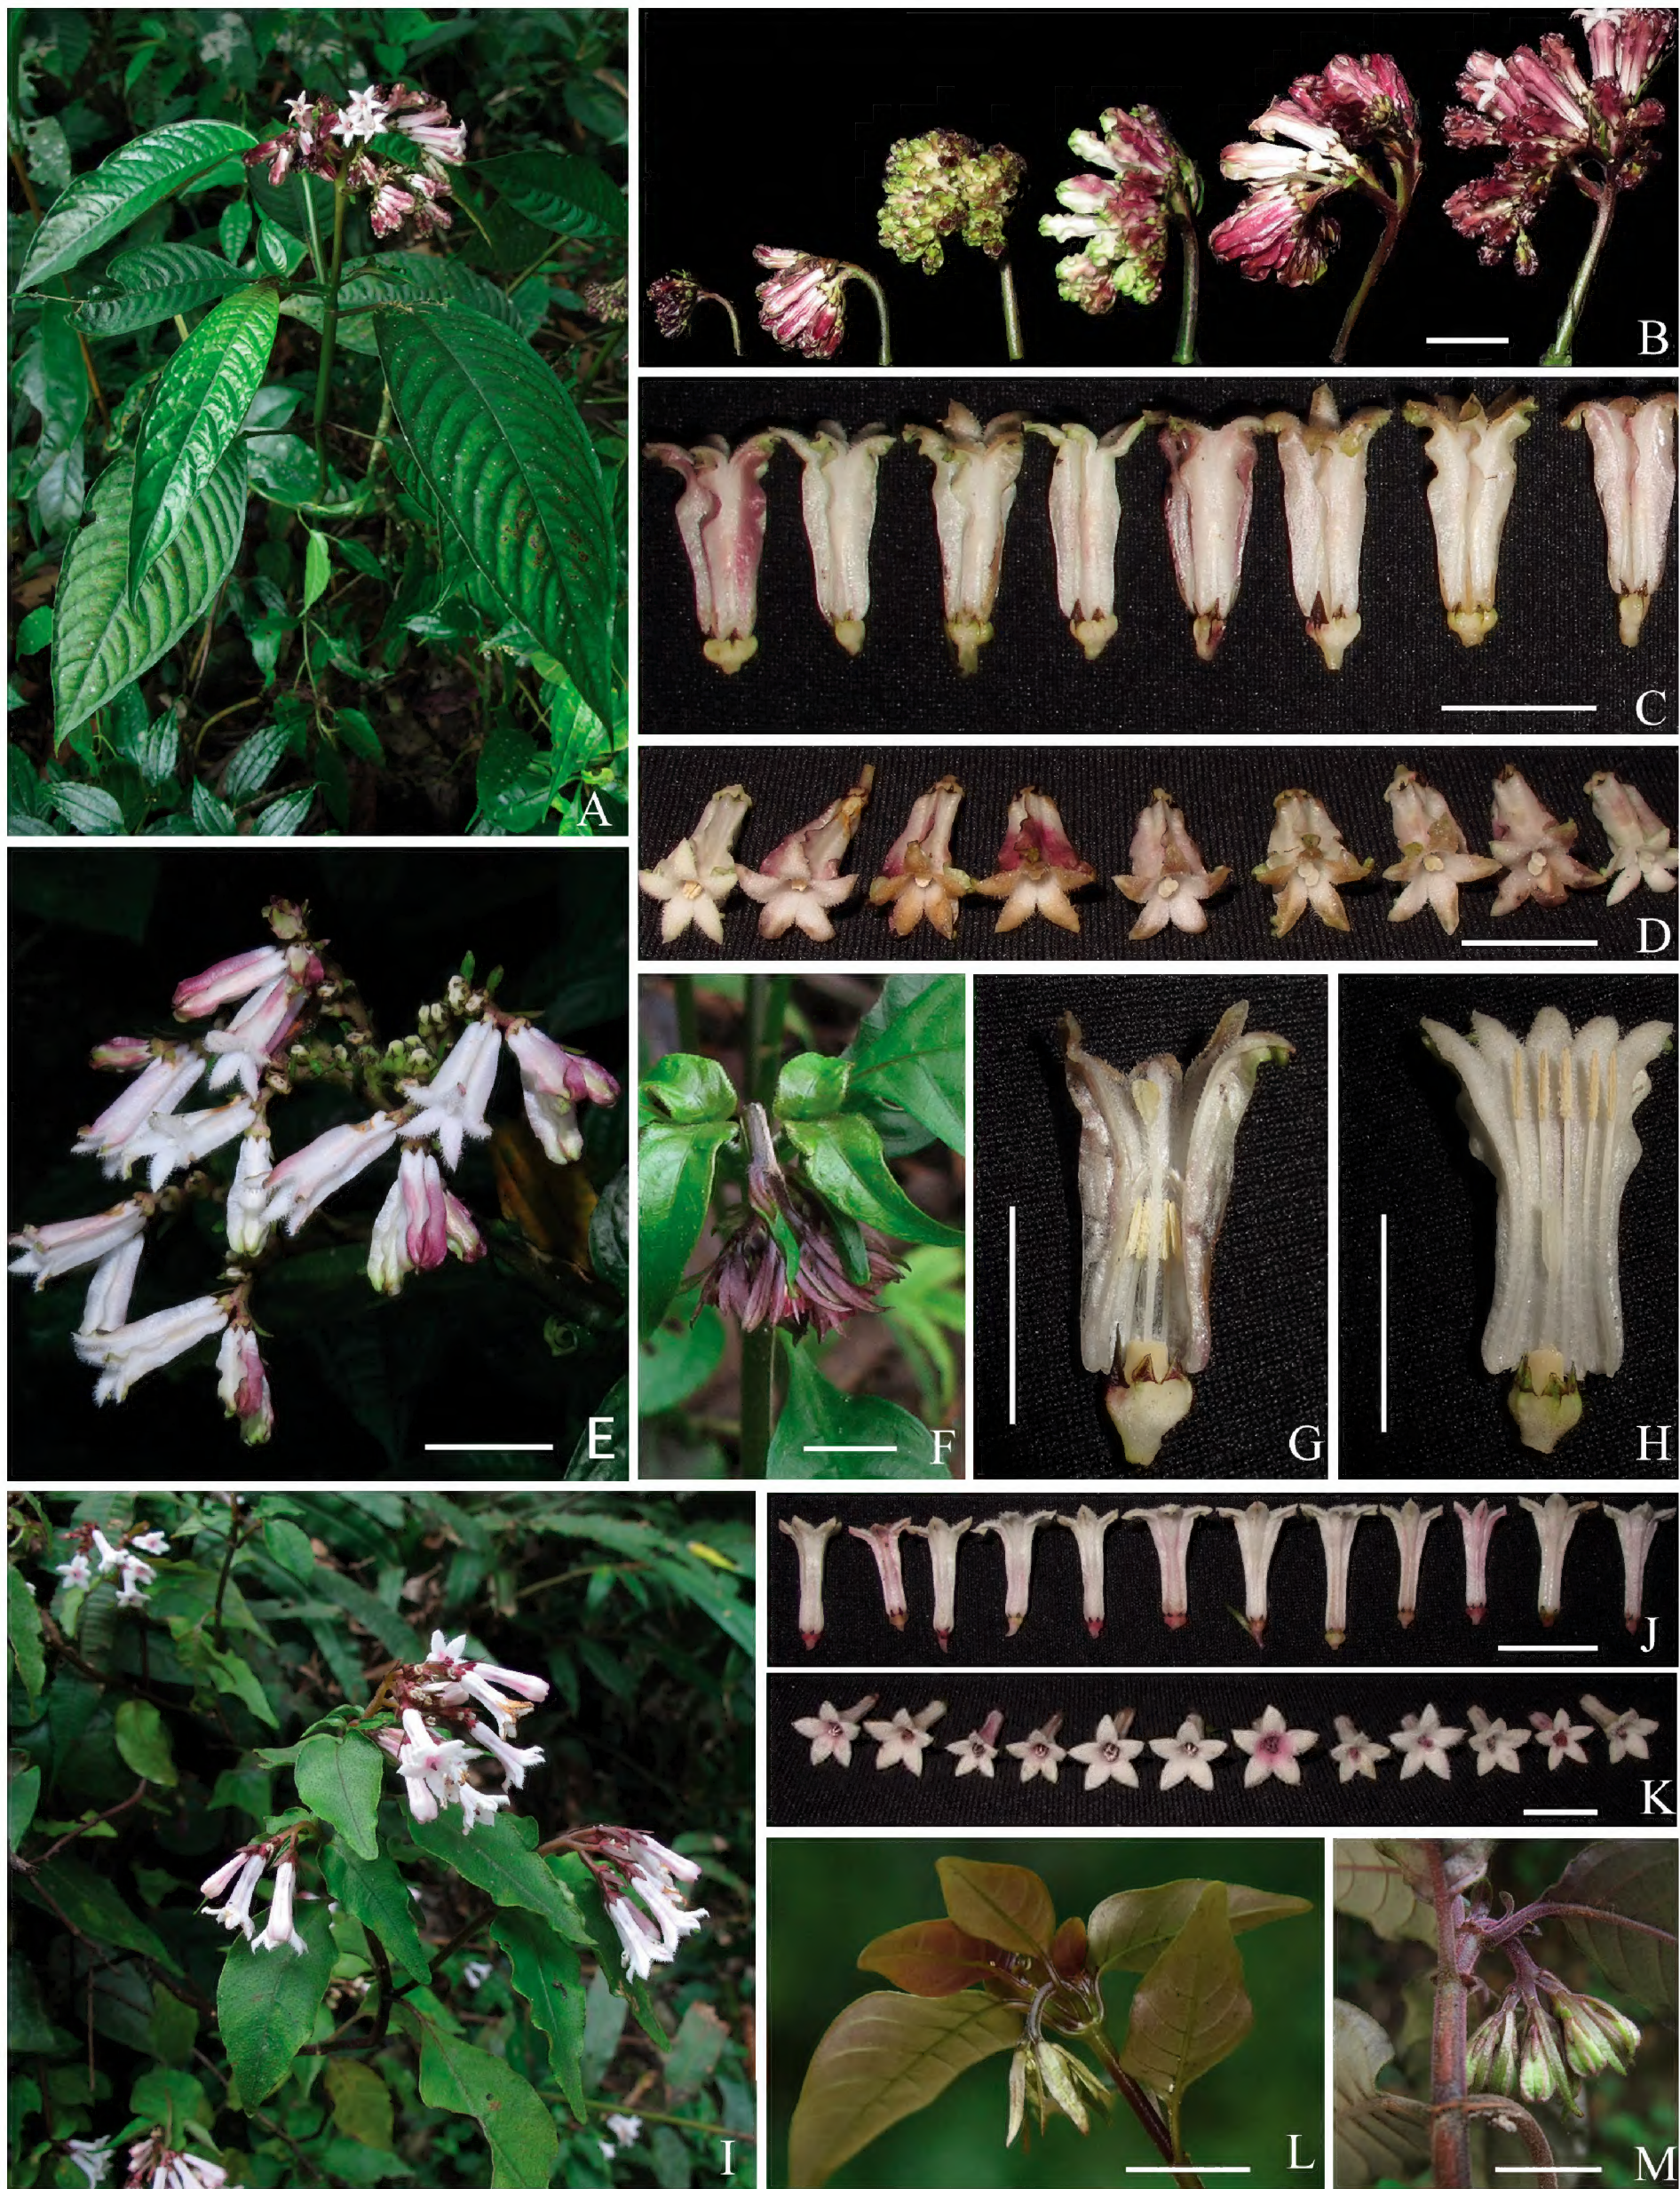

Based on our field investigations of *Ophiorrhiza* in China and careful studies of relevant literature and specimens, about 88% of the known species are confirmed to be distylous plants. At least 52 species have been observed

by us with both long- and short-styled flowers in the same population. Meanwhile, we found that the growth pattern of the inflorescence is relatively stable in Chinese *Ophiorrhiza* species. Nearly half of the Chinese *Ophiorrhiza* species have inflorescences that are erect from the youngest developmental stages (see Fig. 2D, F), whereas the other half have inflorescences drooping when young, then gradually becoming erect (see Fig. 3B, F). In the study of *Ophiorrhiza* species from the Pacific Islands, Darwin (1976) made similar observations and pointed out that the morphology of the inflorescence was taxonomically useful. However, until now, inflorescences have not received sufficient attention in most of the past studies (Lo 1990, 1999; Deb and Mondal 1997; Chen and Taylor 2011).

*Ophiorrhiza reflexa* is most similar to *O. alatiflora*, both of them growing in limestone hills under dense monsoon forests. However, the former differs from the latter mainly by its erect (vs. drooping when young, then erect) inflorescences (Figs 2D, F, 3B, F), 0.5–0.7 mm long and equal calyx lobes (vs. 0.9–1.8, sometimes to 2.5 mm long and unequal, sometimes distinctly, calyx lobes; Figs 2E, K, L, 3C, G, H), strongly reflexed (vs. spreading) corolla lobes at anthesis (Figs 2E, F, K, L, 3C–E, G, H) and corolla outside with straight (vs. obviously undulate) wings from top to middle (vs. along entire length) (Figs 2E, L, 3C, G). Additionally, *Ophiorrhiza reflexa* is morphologically similar to *O. japonica* Blume, the most widely distributed *Ophiorrhiza* species in China. Both of them have caducous stipules, linear-lanceolate bracts, heterostylous flowers and tubular corollas with a villous ring positioned near the middle of the corolla tube in long-styled flowers. However, the new species differs from *O. japonica* by the erect (vs. drooping when young, then erect) and lax (vs. congested or somewhat lax) inflorescences (Figs 2D, F, 3I, L, M), the strongly reflexed (vs. spreading) corolla lobes at anthesis (Figs 2E, I–F, 3I–K) and the longitudinally winged corolla with ca. 0.8 (vs. ca. 0.5) mm wide wings (Figs 2L, 3J). Further distinctive characteristics of the three species are shown in Table 1.

**Table 1.** Morphological comparison of *Ophiorrhiza reflexa*, *O. alatiflora* and *O. japonica*.

	<i>O. reflexa</i>	<i>O. alatiflora</i>	<i>O. japonica</i>
Leaf blade	broadly ovate to elliptic-ovate, 11–17 × 5–8 cm, base broadly cuneate to obtuse, apex acuminate or subacute	ovate or oblong-ovate, 5–13 × 2–7 cm, base cuneate, apex shortly acuminate or subacute	ovate to narrowly lanceolate, 1–11 × 0.7–3.5 cm, base cuneate to obtuse, apex acute to acuminate
Secondary veins	9–13 pairs	7–12 pairs	4–8 pairs
Inflorescence	erect from youngest developmental stages	drooping when young, then gradually erect	drooping when young, then gradually erect
Calyx lobes	equal, 0.5–0.7 mm long	unequal, 0.9–1.8 mm long, sometimes to 2.5 mm long	equal, 0.4–1.2 mm long
Corolla	tubular-funnelform, outside longitudinally winged from top to middle, wings straight, ca. 0.8 mm wide	tubular-funnelform , outside longitudinally winged along entire length, wings undulate, 0.8–1 mm wide	tubular-funnelform to funnelform, outside longitudinal winged from top to middle, wings to 5 mm wide
Corolla lobes	ovate-triangular, reflexed, ca. 4 × 3 mm	triangular, spreading, ca. 3–3.5 × 2.5 mm	triangular to ovate, spreading, ca. 2.5–4 × 2.5–3.5 mm

Acknowledgements

The authors are grateful to the curators of the Herbaria BNU, CSFI, GXMI, HN, HUNN, IBK, IBSC, IMC, KUN, PE, SN, YUYU, SYS and SZ for their permission to examine specimens and to the curators of K and P for providing images of specimens online. We also thank Cheng Du (Shanghai Chenshan Botanical Garden) and Shui-Song Mo from Yulin City for fieldwork assistance and Xin-Yi Zeng (Central South University of Forestry and Technology) for the line drawing.
